netkit - [labs: ospf]

last update: Nov 2013

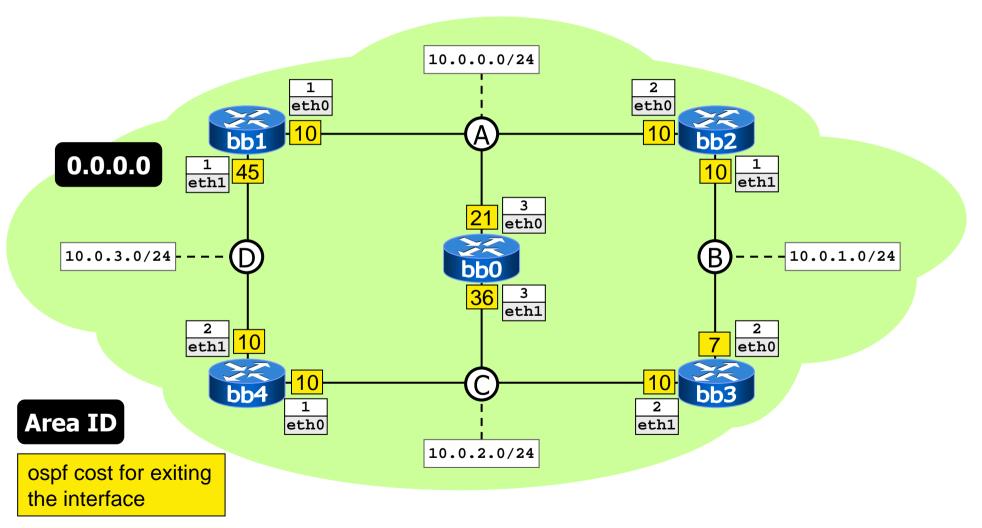

ospf: overview

- each router floods its local state (usable interfaces, reachable neighbors) through the network, using link state advertisements (lsa)
- based on this information, each router builds and maintains a link state database (Isdb) describing the whole network topology
 - identical for (almost) all routers
 - each entry is a router's local state
- each router uses the lsdb to compute a shortest path tree rooted at itself
 - interfaces may be assigned costs
- note: designed to operate on broadcast networks, but has modes to operate on non-broadcast ones

a simple ospf lab

single-area

lab topology

© Computer Networks Research Group Roma Tre

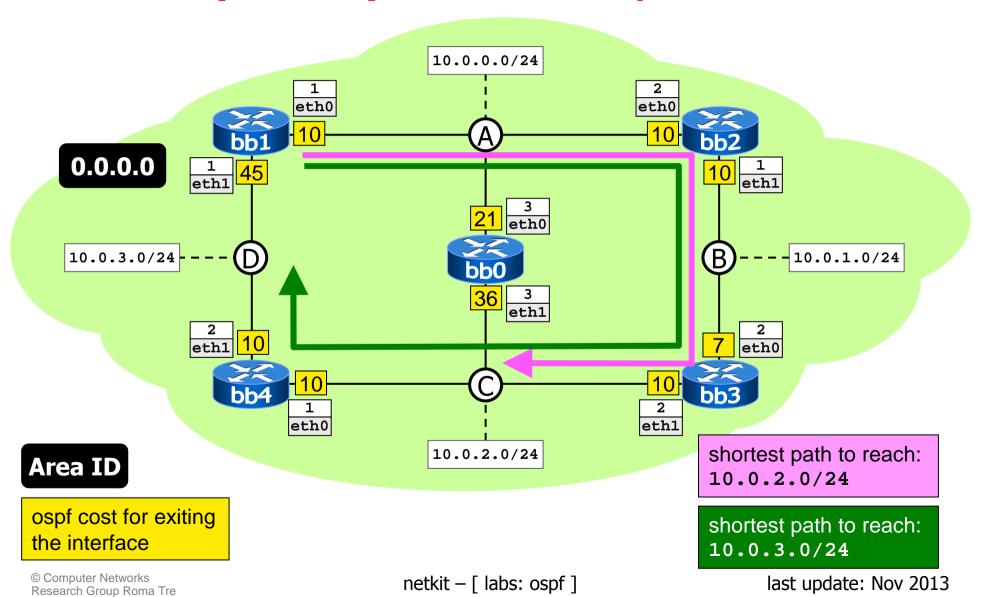

netkit – [labs: ospf]

lab description

- single (backbone) area (0.0.0.0)
- each interface is assigned an ospf cost
 - default: 10
 - we have tweaked the costs to force paths taken by traffic
- to set interface costs:

```
interface eth1
ospf cost 45
```

(some) shortest paths

experiments

- perform traceroutes from/to different interfaces
- perform a traceroute -I from bb1 to 10.0.2.1
 - what path is the traceroute expected to take?
 - what path are ICMP replies expected to take?
- perform a traceroute -I from bb1 to 10.0.3.2
 - what path is the traceroute expected to take?
 - observe the interplay between ospf routes and directly connected networks (i.e., perform a show ip route in zebra)
- try to alter the costs and observe the effect of the changes

experiments

- access the ospfd cli on the various routers and issue the following commands:
 - show ip ospf database
 - show ip ospf neighbor
 - show ip ospf route
- check that the Isdb is exactly the same for all routers

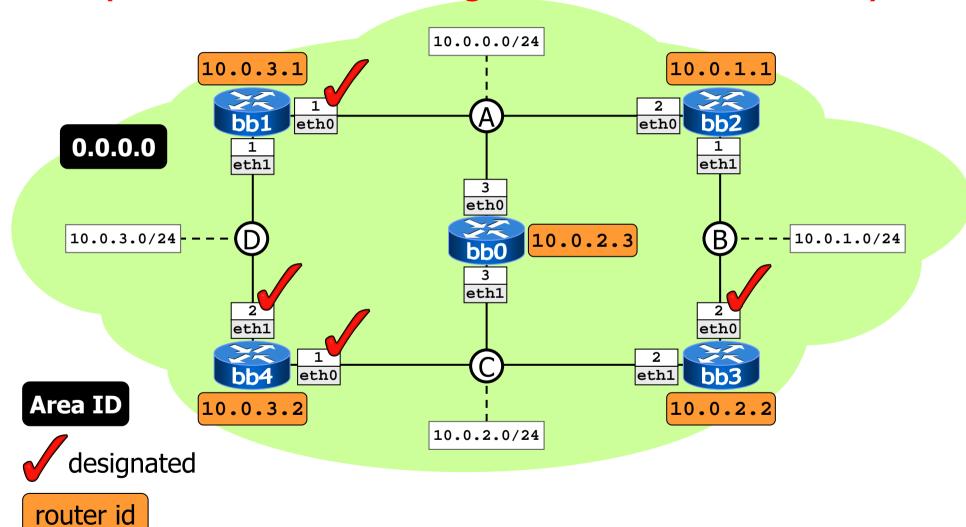

(router interfaces designated for each network)

- for each network, one of the interfaces attached to that network is elected as designated (dr)
- priority-based election, using hello packets
 - the router (interface) sending hello packets with highest piority wins the election
 - break ties on highest router id
 - by default, a router id is the address of one of its interfaces
 - priority∈ [0,255] default priority: 1 priority=0 ⇒ never become a dr
- a backup dr (i.e., the one with second highest priority) is also elected, to quickly recover from dr failures

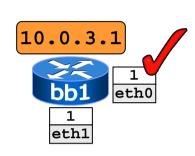

(router interfaces designated for each network)

- a change of the dr is a change in ospf's topology model (new Isas are sent)
- for this reason, the dr is changed infrequently
 - if a router with high priority wakes up and finds that a dr already exists, it accepts that dr

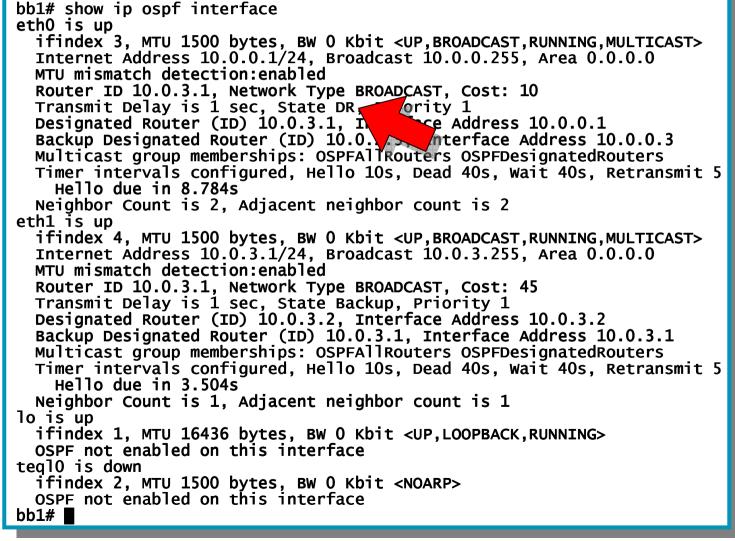

(router interfaces designated for each network)

(router interfaces designated for each network)

 \bigcirc bb1

_ **▲** ×

© Computer Networks Research Group Roma Tre

- by exchanging link state update packets, every router learns about the complete network topology, that is:
 - routers
 - subnets
 - adjacencies between routers and networks

netkit – [labs: ospf]

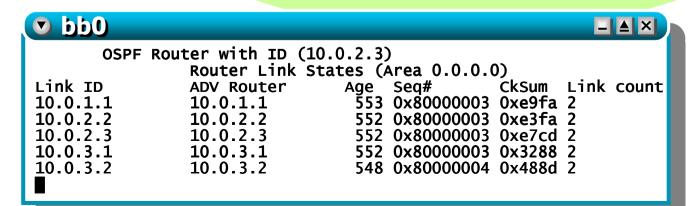

0.0.0.0

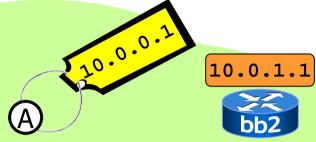

for router Isas, the Link ID is the router's id

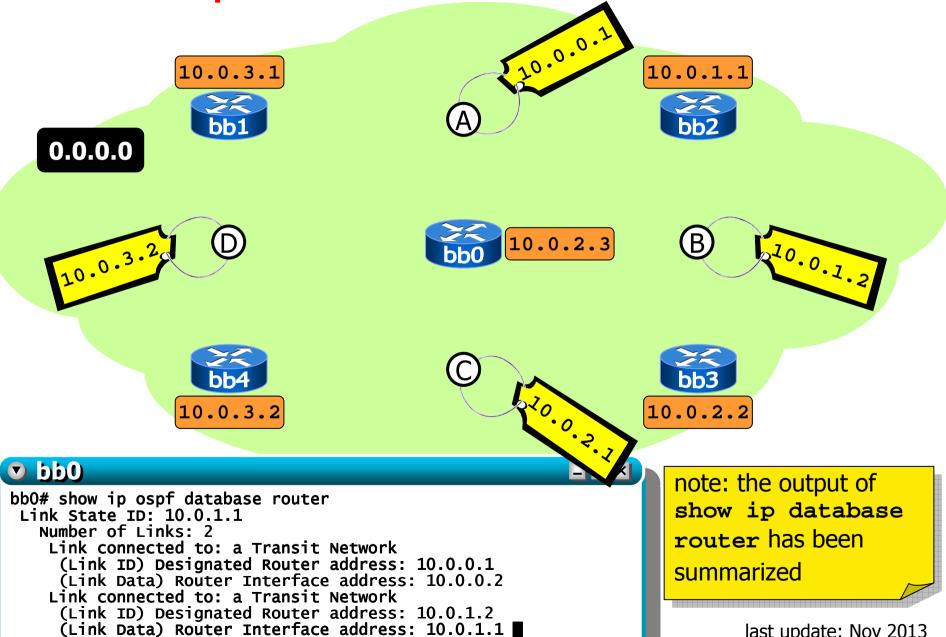

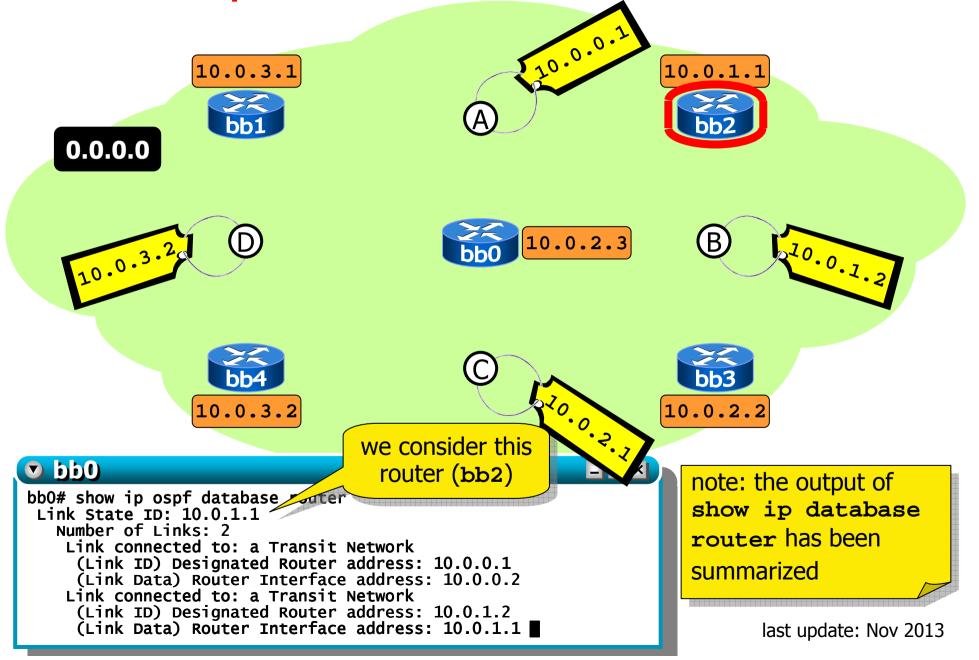

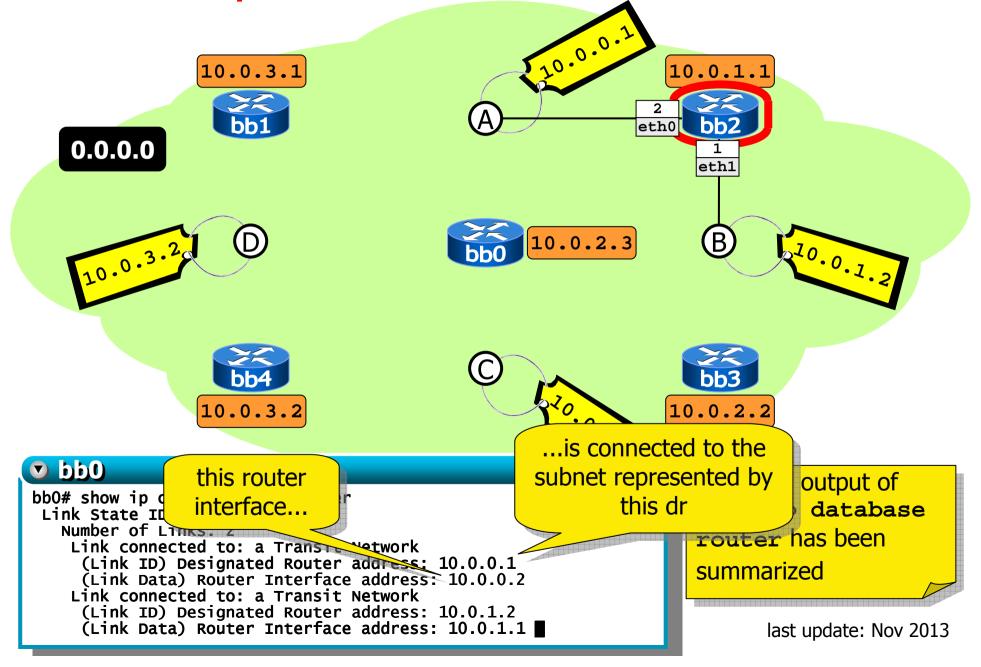

▽ bb0

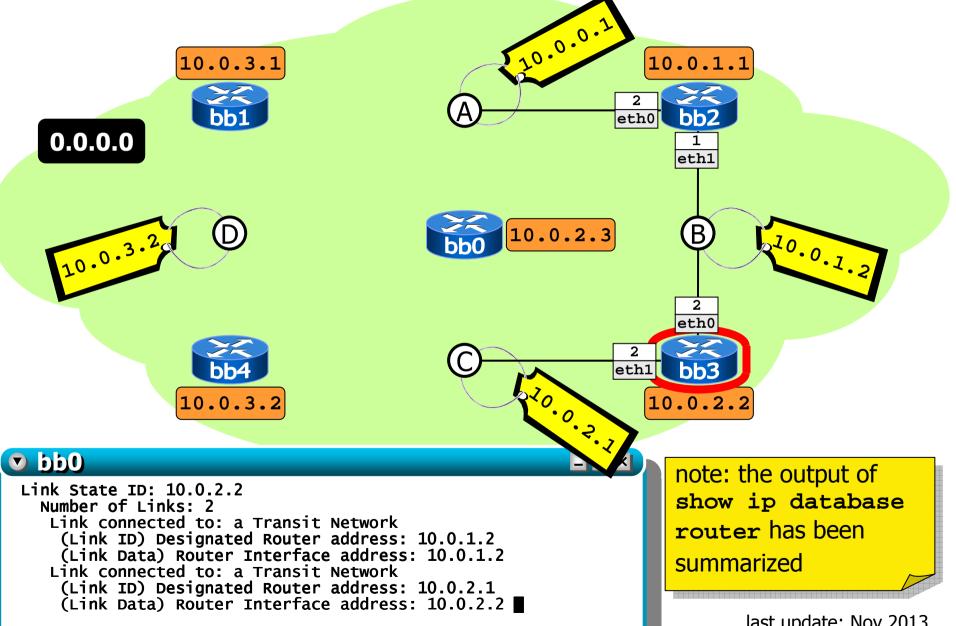

| | Net Link States | (Area 0.0.0.0) | | |
|----------|-----------------|----------------|--------------|--|
| Link ID | ADV Router | Age Seq# | CkSum | |
| 10.0.0.1 | 10.0.3.1 | | 00001 0x6ba8 | |
| 10.0.1.2 | 10.0.2.2 | 559 0x800 | 00001 0x69bb | |
| 10.0.2.1 | 10.0.3.2 | 553 0x800 | 00002 0x729a | |
| 10.0.3.2 | 10.0.3.2 | 553 0x800 | 00001 0x6bb3 | |
| | | | | |

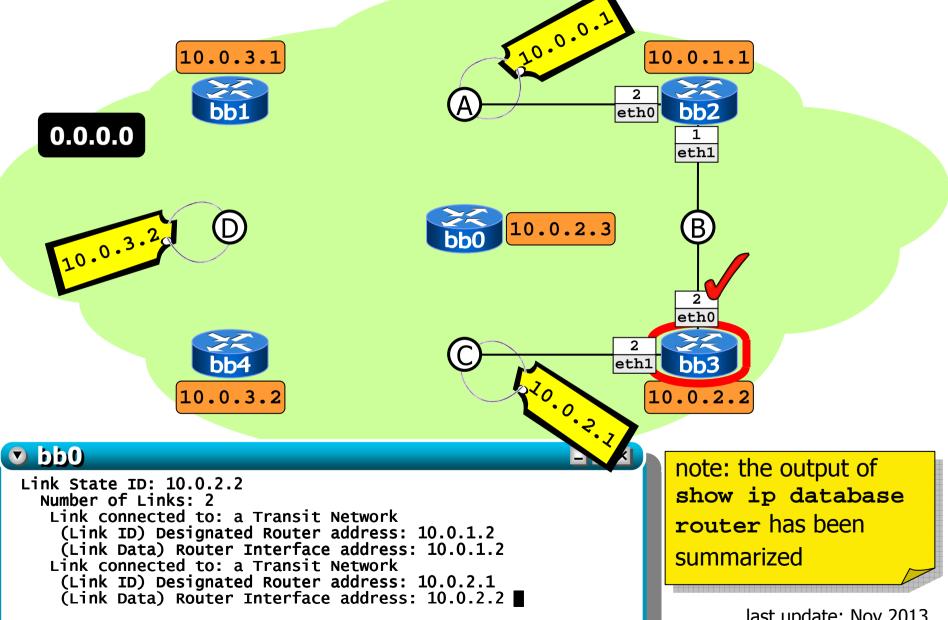

for network Isas, the Link ID is the dr's address

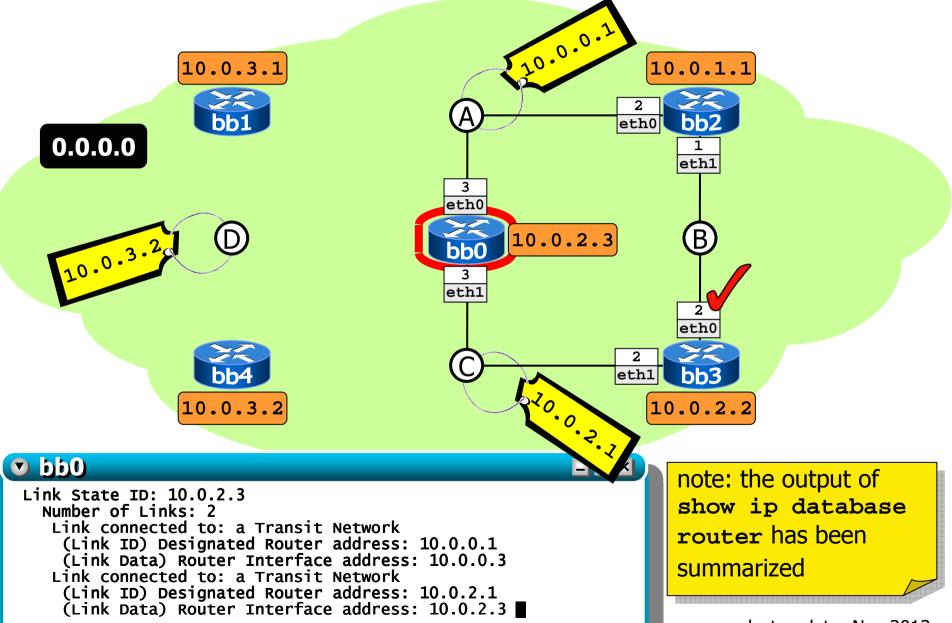

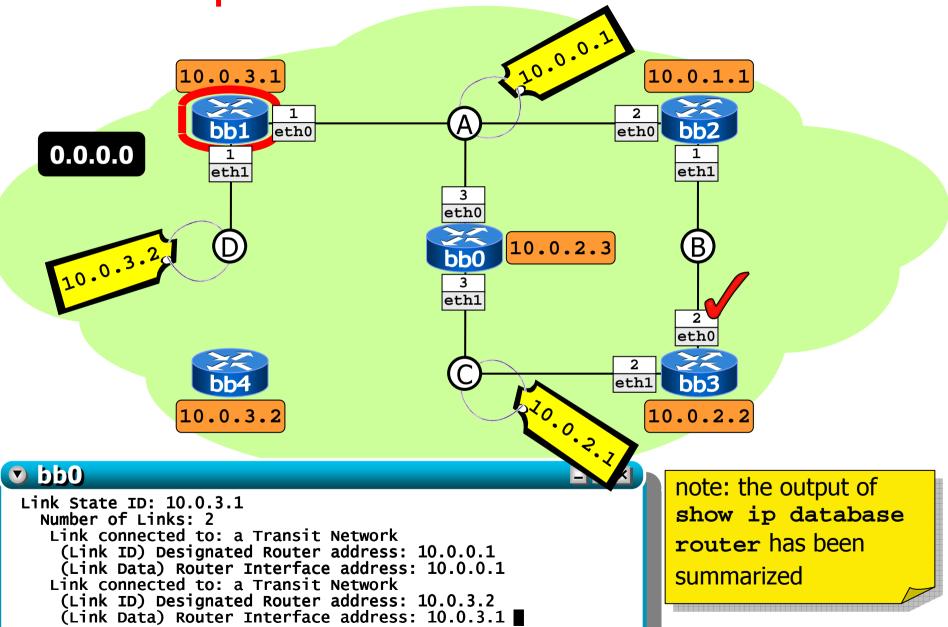

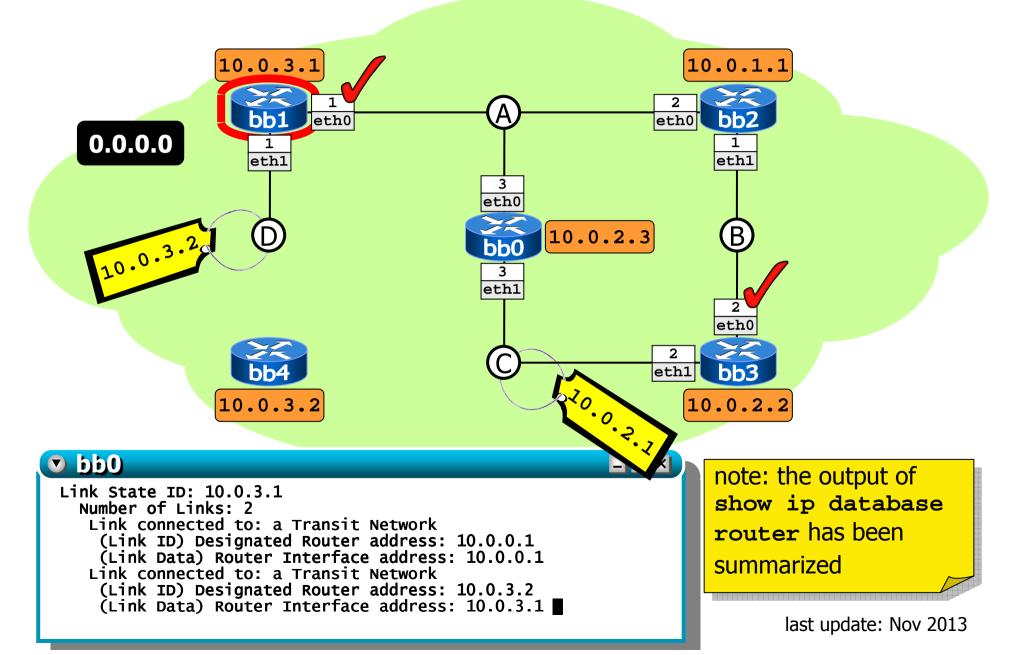

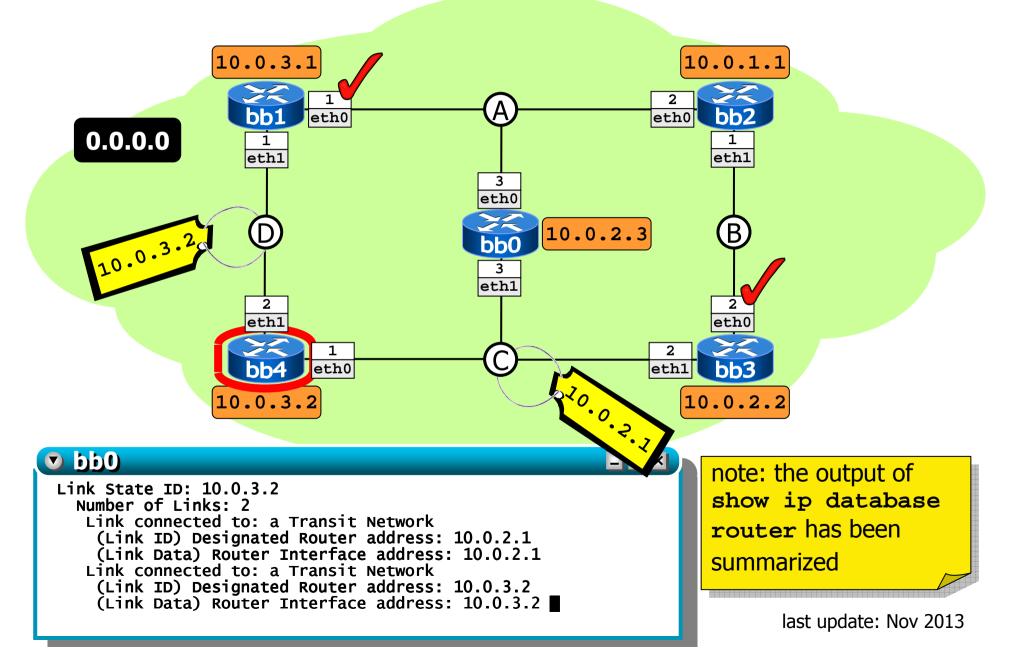

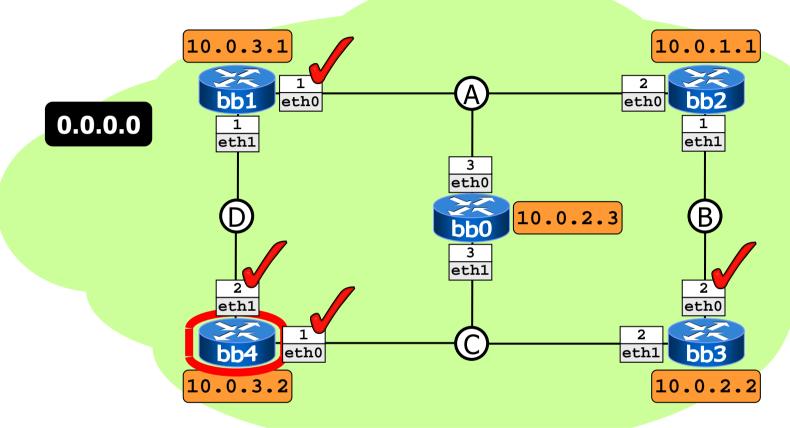

```
Link State ID: 10.0.3.2

Number of Links: 2

Link connected to: a Transit Network

(Link ID) Designated Router address: 10.0.2.1

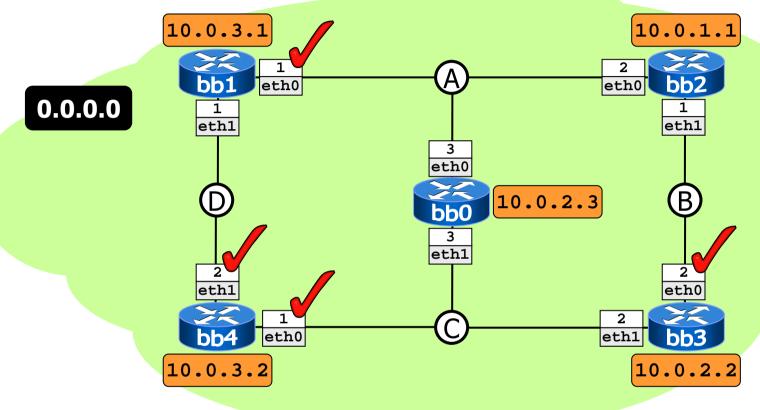

(Link Data) Router Interface address: 10.0.2.1

Link connected to: a Transit Network

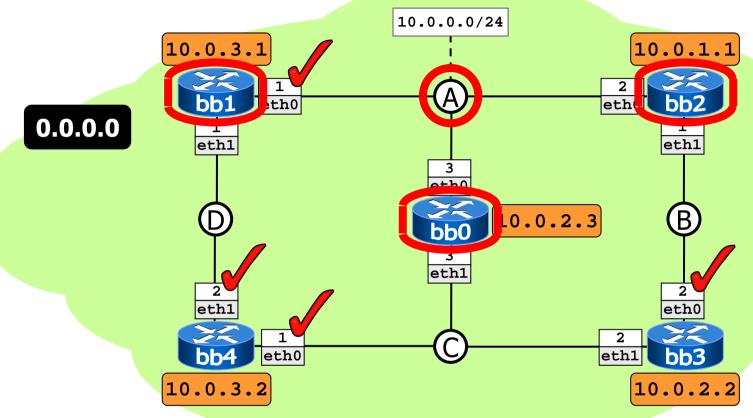

(Link ID) Designated Router address: 10.0.3.2

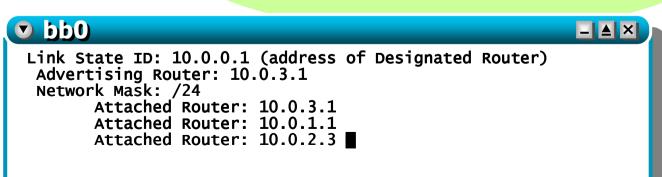

(Link Data) Router Interface address: 10.0.3.2
```

note: the output of show ip database router has been summarized

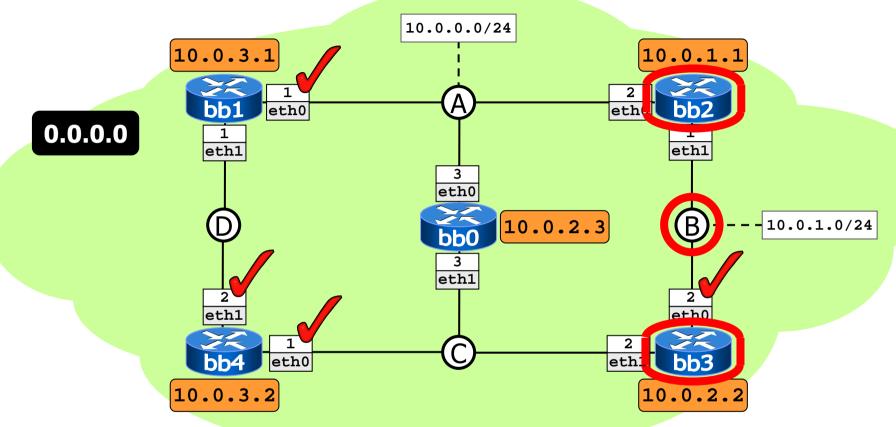

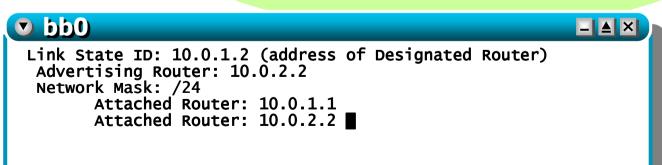

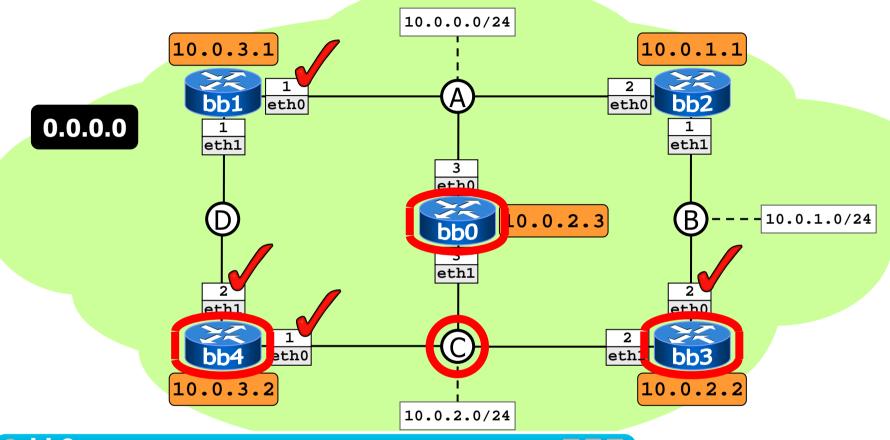

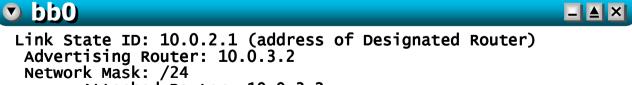

note: the output of show ip database network has been summarized

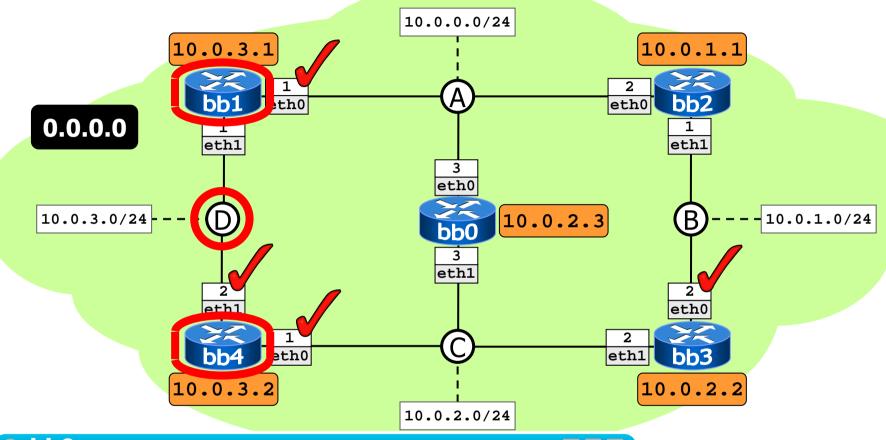

note: the output of show ip database network has been summarized

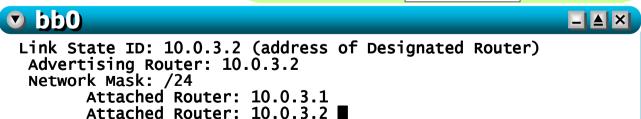

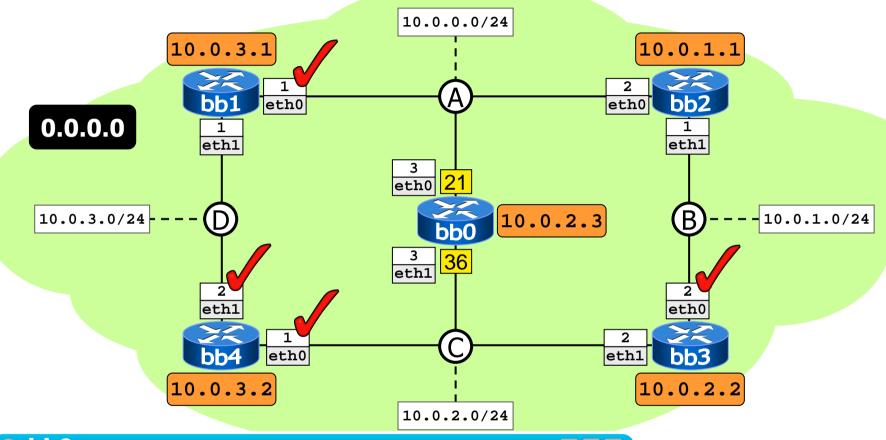

Attached Router: 10.0.3.2
Attached Router: 10.0.2.2
Attached Router: 10.0.2.3

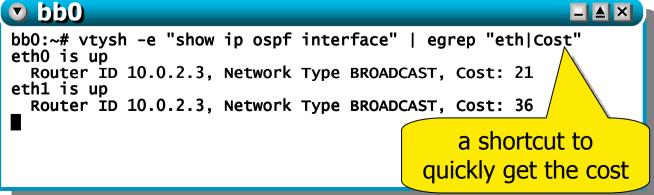

note: the output of show ip database network has been summarized

note: the output of show ip database network has been summarized

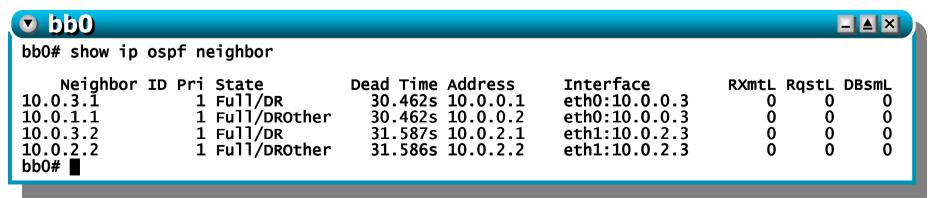

ospf interface costs can be queried on all routers

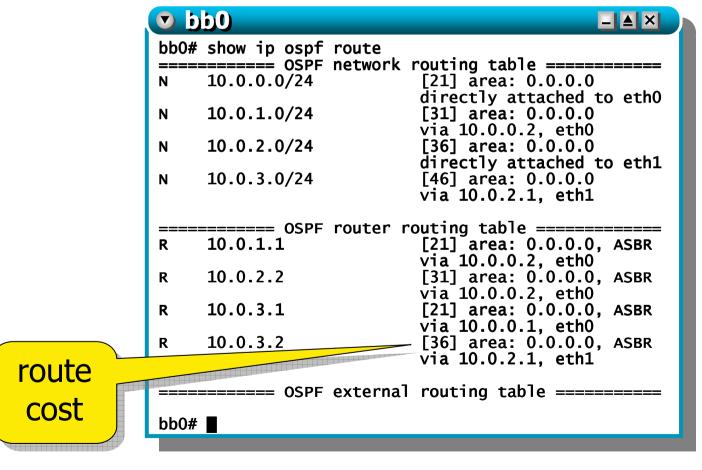

neighborhood

- router neighbors can be shown by using the show ip ospf neighbor command
- note: lsas are only sent between neighbors in Full state (i.e., capable of a bidirectional exchange of information); reaching the Full state requires that:
 - neighbors have been discovered (using hello packets)
 - bidirectional communication is possible
 - a designated router has been elected
- once reached, routers immediately synchronize their lsdbs

ospf routing table

the ospf routing table can be dumped by using show ip ospf route

- issue the show ip ospf database and show ip ospf neighbor commands on different routers
- capture and look at exchanged ospf packets using tcpdump

- bring down a single network interface using ifconfig
 - the change is immediately propagated by the router inside Isa packets
 - routing tables are immediately updated
 (show ip ospf route)

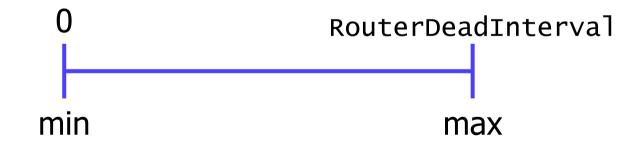

- case #1: link fault
 - bring down a single network interface using ifconfig
 - the change is immediately propagated by the router inside Isa packets
 - routing tables are immediately updated
 (show ip ospf route)
 - the Isdb is handled a little differently...

- case #1: link fault
 - bring down a single network interface using ifconfig
 - if this brings down a dr, the information is immediately flushed from the lsdb(s)...
 - ...and eventually reannounced when a dr is re-elected
 - otherwise, ospf waits expiry of the RouterDeadInterval timer (default: 40s) before removing the adjacency from the lsdb (show ip ospf database network)
 - note: networks that are connected to one router only, called <u>stub networks</u>, are only visible using <u>show ip</u>
 ospf database router

bring down a single network interface using ifconfig

overall reaction time (estimated)

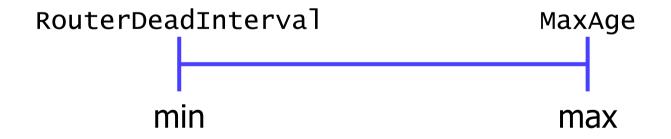

- case #2: router fault
 - bring down a router (by crashing it or by shutting down all its interfaces simultaneously)
 - the router has no chance to propagate Isas
 - the change cannot be immediately propagated
 - neighboring routers can only realize it (and update routing tables) after expiry of the RouterDeadInterval timer

- case #2: router fault
 - bring down a router (by crashing it or by shutting down all its interfaces simultaneously)
 - after the change has been propagated...
 - ...Isdb information about networks for which the failed router was not dr is immediately flushed from other routers' Isdbs
 - the dr takes care of sending appropriate Isas
 - ...Isdb information about networks for which the failed router was dr (including those where a dr will be re-elected) and about routers is more "tough"
 - ospf waits for the Isa to expire (expiration happens when the age of the Isa reaches the MaxAge value of 1 hour) before taking any actions

case #2: router fault

 bring down a router (by crashing it or by shutting down all its interfaces simultaneously)

overall reaction time (estimated)

lab: ospf-multiarea

ospf areas

OP SECRET RESEARCH FACILITY

NO TRESPASSING

VIOLATORS WILL VANISH

- an abstraction that simplifies
 administration and improves scalability
 - the topology of an area is invisible from the outside
 - routers internal to a given area don't see the detailed external topology
- each area runs a separate instance of the link state routing algorithm
 - all routers in an area construct the same Isdb
 - each router keeps a distinct lsdb for each area it belongs to

ospf areas

- AREA 51
 TOP SECRET RESEARCH FACILITY

 NO TRESPASSING

 VIOLATORS WILL VANISH WITHOUT A TRACE
- identified by a 32-bit number,
 often in dotted decimal notation (1.2.3.4)
 - different interfaces of the same router can be assigned to different areas
 - each
 - router interface...
 - network...
 - router adjacency...
 - ...is associated with a single area

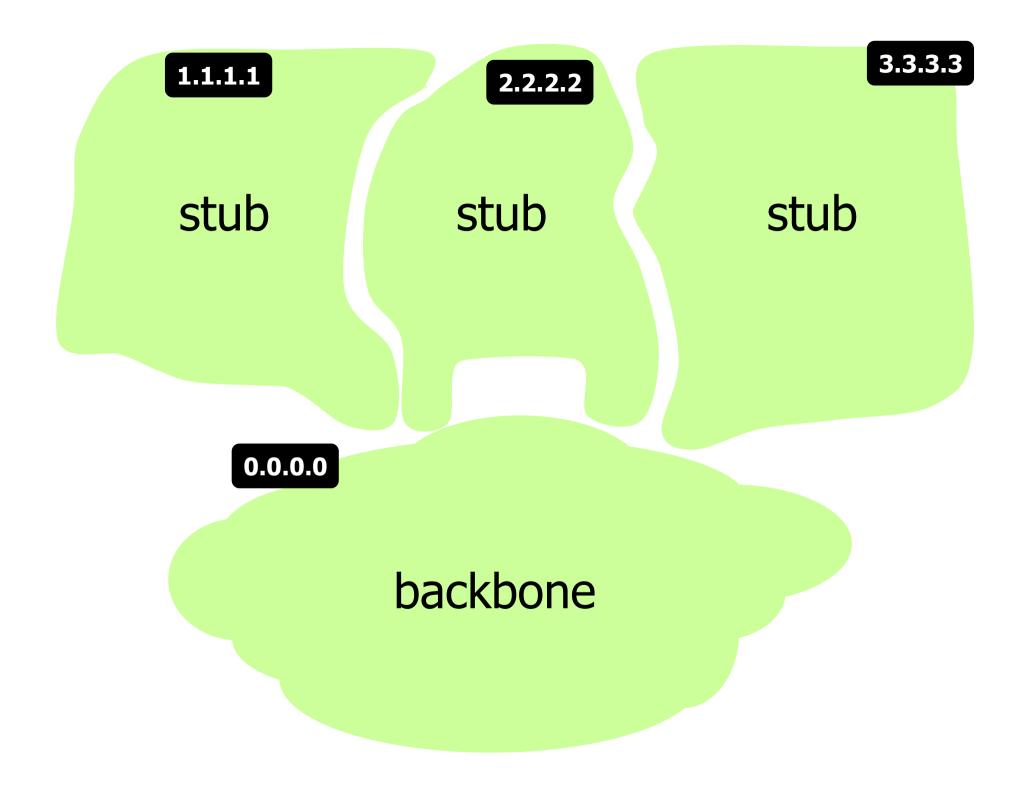

- backbone (0.0.0.0)
 - must be (virtually) connected
 - all other areas are connected to it
 - contains all the area border routers

stub

- does not receive advertisements of external routes
- internal nodes are offered a default route
- cannot contain autonomous system boundary routers
- the backbone can't be a stub area

transit

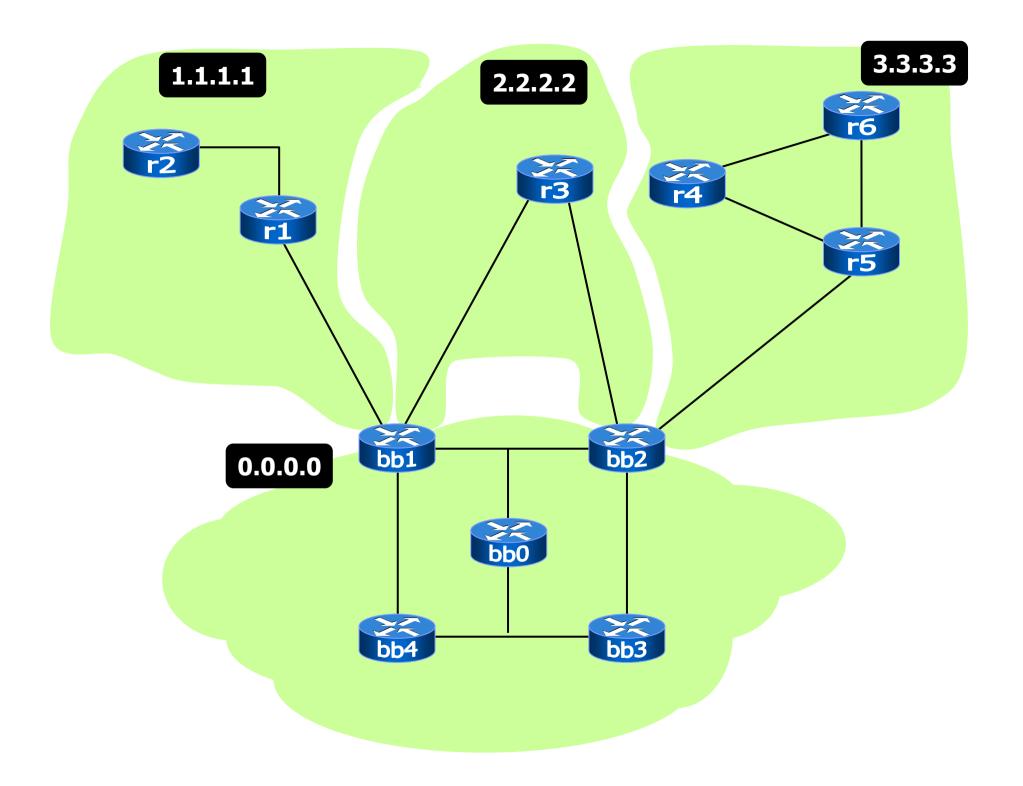

used to pass traffic from one adjacent area to another, via virtual links

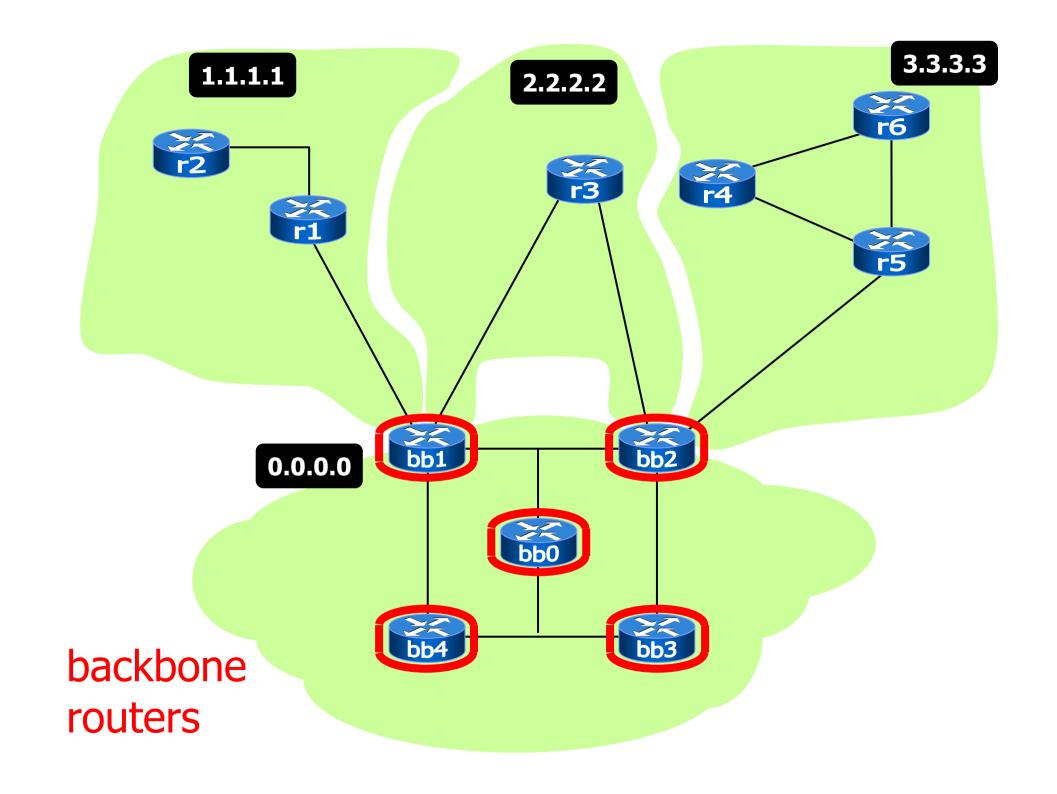

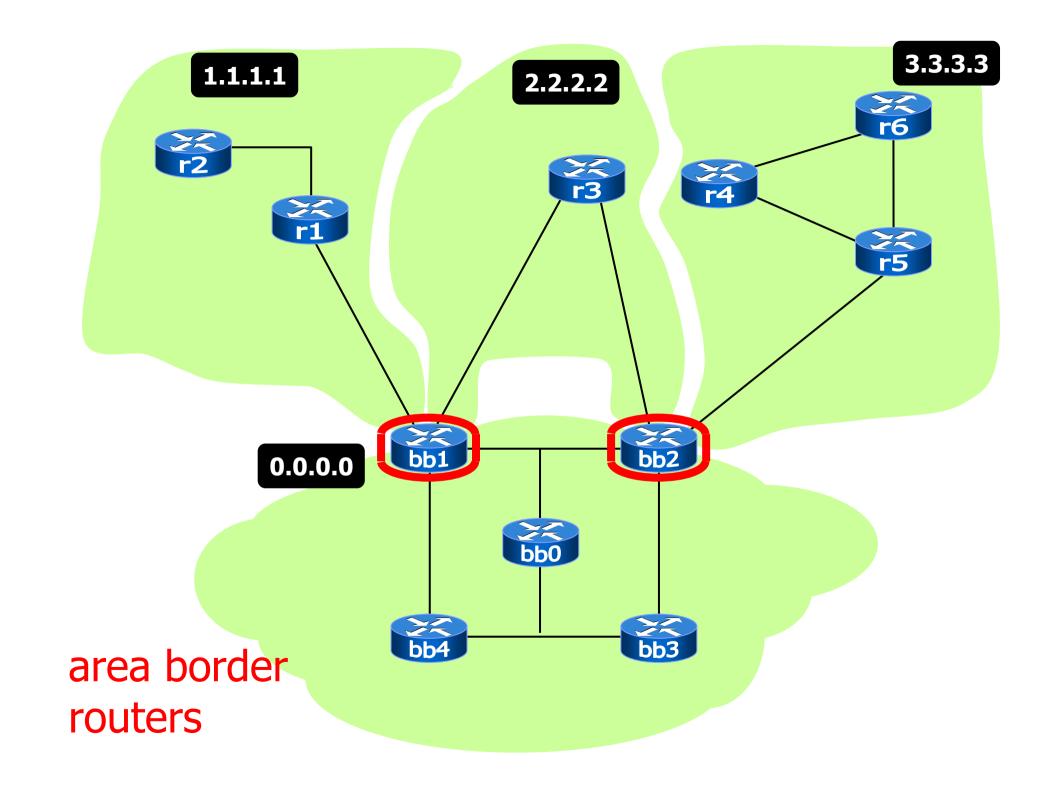

router types

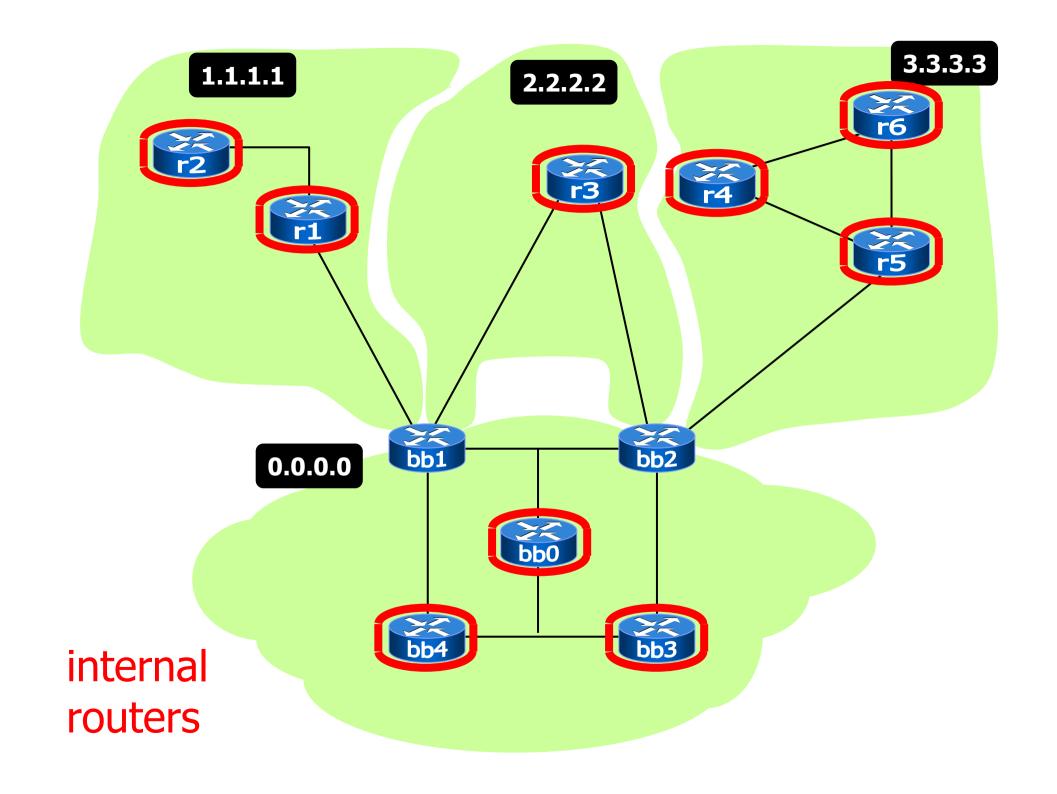

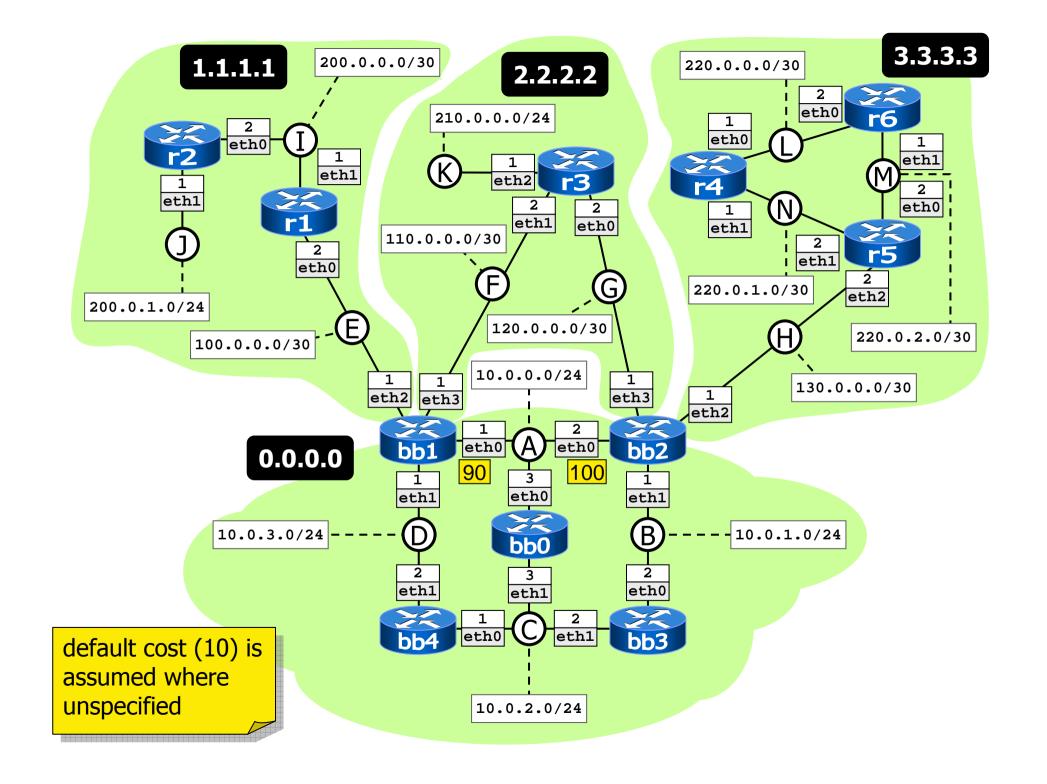

- internal router
 - all interfaces belong to the same area
- area border router (abr)
 - connects one or more areas to the backbone
 - keeps multiple Isdbs, one for each area
- backbone router
 - has at least one interface connected to the backbone
 - an abr is always a backbone router
- autonomous system boundary router (asbr)
 - imports and floods routing information from other routing protocols (typically, bgp)
- note: a router can be of more than one type

area configuration

- area information is found in two places
 - when enabling ospf on router interfaces network 200.0.0.0/16 area 1.1.1.1
 - when specifying the area type (not required for the backbone)

area 1.1.1.1 stub

- there are 4 path types
 - 1.intra-area
 - 2.inter-area
 - 3.external type 1
 - 4.external type 2
- types can coexist in the same network
- each type is preferred over the following ones

- intra-area paths
 - calculated using the shortest-path tree

- inter-area paths
 - abrs inject summary information inside each area, to make it aware of available destinations in other areas

- such information includes the cost of the shortest path from the abr to the destination
- if multiple subnets are summarized into a single network, the route cost will be the maximum cost to any of the component subnets
- an inter-area path is always composed of:
 - an intra-area path from the source to the abr
 - a backbone path between the source and destination areas
 - an intra-area path to the destination

 external paths are learned from other routing protocols (e.g., bgp)

- type 1: the cost is expressed in terms of
 - the external (bgp) route cost +
 - the ospf cost to the asbr
- type 2: the cost is expressed in terms of
 - the external (bgp) route cost only (distance to the asbr is only used to break ties)

check that routers know detailed topology information only about their own area

        Attached Router: 200.0.1.1
r2#
```

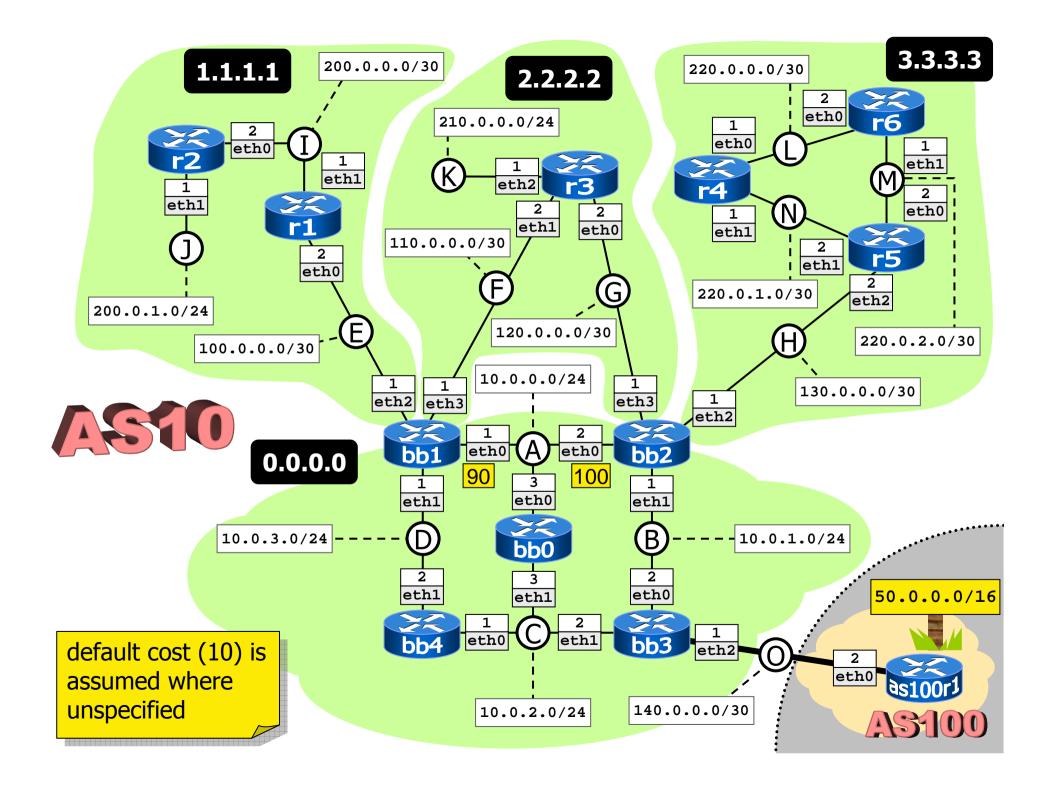

- check what routers know about the outside of the area, using the show ip ospf database summary command
 - in particular, check the Metric values, that show how far away the destination is from the advertising abr
- check that routers in stub areas are offered a default route, whereas routers in the backbone are not
 - also check what Metric is assigned to the default route

- experiment ospf's recovery capabilities
 - when multiple equal cost routes are available, ospf keeps all of them
 - check it by verifying what r3 knows about the default route

- experiment ospf's recovery capabilities
 - when multiple equal cost routes are available, ospf keeps all of them
 - check it by verifying what r3 knows about the default route
 - now bring bb1's eth3 down using ifconfig, wait a few seconds and check how the routing is changed
 - bring bb1's eth3 back up and check again how the routing is changed

lab: ospf-complex

lab description

- same as multiarea + some information is injected via bgp from an external as
 - also, abrs are configured to just inject the default route

```
area 1.1.1.1 stub no-summary
```

- perform the same experiments as for the multiarea lab
 - in addition, check asbr information using show ip ospf database asbr-summary
 - also check that such information is not propagated inside stub areas

a quick note about stub networks

- "stub" = not used for transit
- three possible situations:
